Extensible Markup Language (XML)

Outline

Objectives

- In this lesson, you will learn:
  - To understand XML.
  - To be able to mark up data using XML.
  - To become familiar with the types of markup languages created with XML.
  - To understand the relationships among DTDs, Schemas and XML.
  - To understand the fundamentals of DOM-based and SAX-based parsing.
  - To understand the concept of an XML namespace.
  - To be able to create simple XSL documents.
  - To become familiar with Web services and related technologies.

20.1 Introduction

- XML (Extensible Markup Language)
  - Derived from Standard Generalized Markup Language (SGML)
  - Open technology for electronic data exchange and storage
  - Create other markup languages to describe data in structured manner
  - XML documents
    - Contain only data, not formatting instructions
    - Highly portable
    - XML parser
    - Support Document Object Model or Simple API XML
    - Document Type Definition (DTD, schema)
      - XML document can reference another that defines proper structure
  - XML-based markup languages
    - XML vocabularies

20.2 Structuring Data

- XML declaration
  - Value `version`
    - Indicates the XML version to which the document conforms
- Root element
  - Element that encompasses every other elements
- Container element
  - Any element contains other elements
- Child elements
  - Elements inside a container element
- Empty element `flag`
  - Does not contain any text
- DTD documents
  - End with `.dtd` extension

```xml
<?xml version = "1.0"?>

<!-- Fig. 20.1: article.xml      -->

20.3 XML Namespaces

- XML
  - Allows document authors to create custom elements
  - Naming collisions
  - XML namespace
    - Collection of element and attribute names
    - Uniform resource identifier (URI)
      - Uniquely identifies the namespace
      - A string of text for differentiating names
    - Any name except for reserved namespace `xml`
    - `Directory`
      - Root element and contains other elements

```xml
<?xml version = "1.0"?>

<!-- Fig. 20.4 : namespace.xml -->
<!-- Demonstrating Namespaces  -->

<text:directory xmlns:text = "urn:deitel:textInfo"
   xmlns:image = "urn:deitel:imageInfo">

   <text:file filename = "book.xml">
      <text:description>A book list</text:description>
   </text:file>

   <image:file filename = "funny.jpg">
      <image:description>A funny picture</image:description>
      <image:size width = "200" height = "100"/>
   </image:file>

</text:directory>
```

```xml
<?xml version = "1.0"?>

<!-- Fig. 20.5 : defaultnamespace.xml -->
<!-- Using Default Namespaces         -->

<directory xmlns = "urn:deitel:textInfo"
   xmlns:image = "urn:deitel:imageInfo">

   <file filename = "book.xml">
      <description>A book list</description>
   </file>

   <image:file filename = "funny.jpg">
      <image:description>A funny picture</image:description>
      <image:size width = "200" height = "100"/>
   </image:file>

</directory>
```

20.4 Document Type Definitions (DTDs) and Schemas

- Two types of documents for specifying XML document structure
  - Document Type Definition (DTDs)
  - Schemas

20.4.1 Document Type Definitions

- Enables XML parser to verify whether XML document is valid
- Allow independent user groups to check structure and exchange data in standardized format
- Expresses set of rules for structure using EBNF grammar
- `ELEMENT` type declaration
  - Defines rules
- `ATTLIST` attribute-list declaration
  - Defines an attribute

```

Outline

letter.dtd
(1 of 1)

20.4.2 W3C XML Schema Documents

- Schemas
  - Specify XML document structure
  - Do not use EBNF grammar
  - Use XML syntax
  - Can be manipulated like other XML documents
  - Require validating parsers
  - XML schemas
    - Schema vocabulary the W3C created
    - Recommendation
    - Schema valid
      - XML document that conforms to a schema document
      - Use `.xsd` extension

20.4.2 W3C XML Schema Documents

- Root element `schema`
  - Contains elements that define the XML document structure
  - `targetNamespace`
    - Namespace of XML vocabulary the schema defines
  - `element` tag
    - Defines element to be included in XML document structure
  - `name` and `type` attributes
    - Specify element's name and data type respectively
  - Built-in simple types
    - `date`, `int`, `double`, `time`, etc

20.4.2 W3C XML Schema Documents

- Two categories of data types
  - Simple types
    - Cannot contain attributes or child elements
  - Complex types
    - May contain attributes and child elements
    - `complexType`
      - Define complex type
    - Simple content
      - Cannot have child elements
    - Complex content
      - May have child elements

```xml
<?xml version = "1.0"?>

<!-- Fig. 20.7 : book.xml       -->
<!-- Book list marked up as XML -->

<deitel:books xmlns:deitel = "http://www.deitel.com/booklist">
   <book>
      <title>XML How to Program</title>
   </book>
   <book>
      <title>C How to Program</title>
   </book>
   <book>
      <title>Java How to Program</title>
   </book>
   <book>
      <title>C++ How to Program</title>
   </book>
   <book>
      <title>Perl How to Program</title>
   </book>
</deitel:books>

20.5 XML Vocabularies

- W3C XML Schema
- XSL (Extensible Stylesheet Language)
- MathML (Mathematical Markup Language)
- SVG (Scalable Vector Graphics)
- WML (Wireless Markup Language)
- XBRL (Extensible Business Reporting Language)
- XUL (Extensible User Interface Language)
- PDML (Product Data Markup Language)

20.5.1 MathML

- Describe mathematical notations and expressions
- MathML markup
  - Content markup
    - Provides tags that embody mathematical concepts
    - Allows programmers to write mathematical notation specific to different areas of mathematics
    - Distinguishes between different uses of same symbol
  - Presentation markup
    - Directed towards formatting and displaying mathematical notation

```
1  <?xml version="1.0"?>

20.5.3 MusicXML

- Music distribution
- Simplifies exchange of musical scores over Internet
- Developed by Recordare
- Mark up all type of music
- DTD
  - Less powerful than Schema
  - Simpler to program
- Relies heavily on elements rather than attributes

20.5.3 MusicXML

Fig. 20.15 MusicXML markup rendered by Finale 2003 (Courtesy of MakeMusic! Inc.).

20.5.4 RSS

- RDF Site summary
- Popular and simple XML format designed to share headlines and Web content between Web sites
- RSS file
  - RSS feed
  - Container `rss` element
    - Denotes the RSS version
  - Container channel elements
    - Descriptive tags
    - Item elements
      - Describe the news or information
      - `title` element
      - `description` element
      - `link` element

20.5.5 Other Markup Languages

Markup language	Description
VoiceXML	The VoiceXML Forum founded by AT&T, IBM, Lucent and Motorola developed VoiceXML. It provides interactive voice communication between humans and computers through a telephone, PDA (personal digital assistant) or desktop computer. IBM's VoiceXML SDK can process VoiceXML documents. Visit `www.voicexml.org` for more information on VoiceXML. We introduce VoiceXML in Chapter 29, Accessibility.
Synchronous Multimedia Integration Language (SMIL)	SMIL is an XML vocabulary for multimedia presentations. The W3C was the primary developer of SMIL, with contributions from some companies. Visit `www.w3.org/AudioVideo` for more on SMIL. We introduce SMIL in Chapter 28, Multimedia.
Research Information Exchange Markup Language (RIXML)	RIXML, developed by a consortium of brokerage firms, marks up investment data. Visit `www.rixml.org` for more information on RIXML.
ComicsML	A language developed by Jason MacIntosh for marking up comics. Visit `www.jmac.org/projects/comics_ml` for more information on ComicsML.
Geography Markup Language (GML)	OpenGIS developed the Geography Markup Language to describe geographic information. Visit `www.opengis.org` for more information on GML.
Extensible User Interface Language (XUL)	The Mozilla Project created the Extensible User Interface Language for describing graphical user interfaces in a platform-independent way.

Fig. 20.17 Various markup languages derived from XML.

20.6 Document Object Model (DOM)

- Document Object Model (DOM) tree
  - Nodes
  - Parent node
    - Ancestor nodes
  - Child node
    - Descendant nodes
    - Sibling nodes
  - One single root node
    - Contains all other nodes in document
- Application Programming Interface (API)

20.6 Document Object Model (DOM)

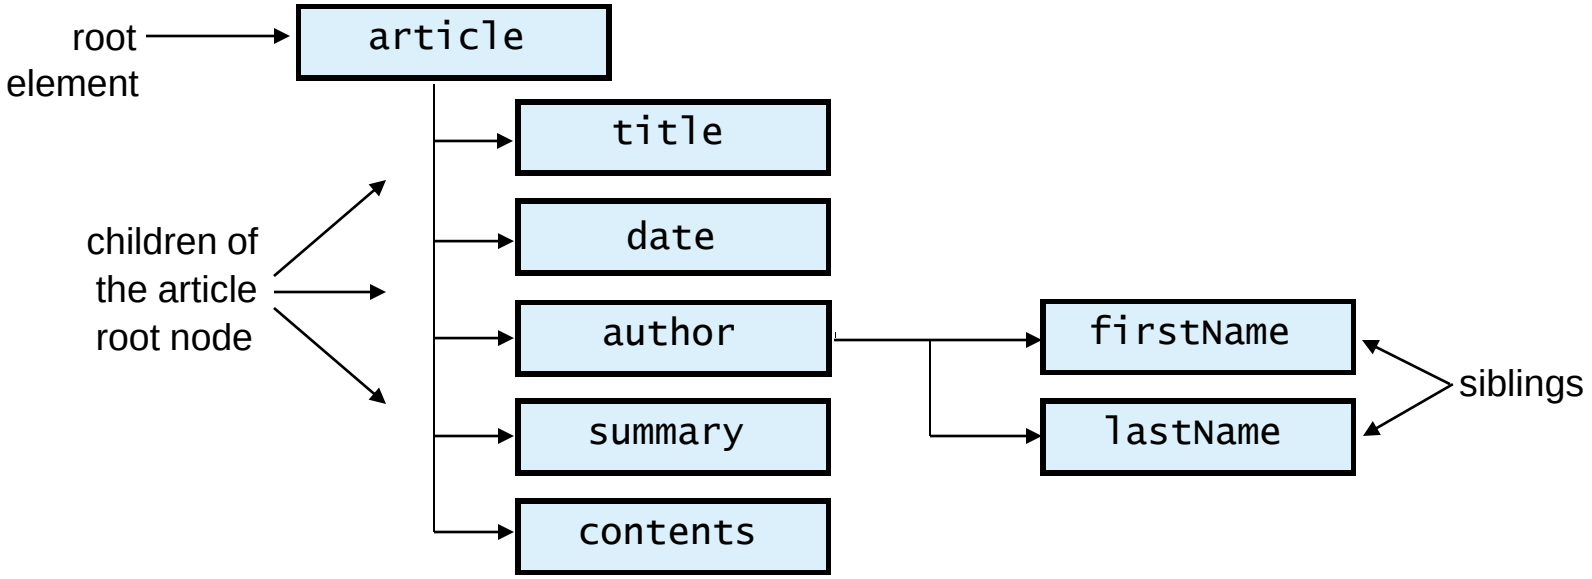

Fig. 20.18 Tree structure for article.xml.

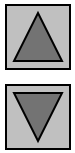
20.7 DOM Methods

- `nodeName`
  - Name of an element, attribute, or so on
- `NodeList`
  - List of nodes
  - Can be accessed like an array using method `item`
- Property `length`
  - Returns number of children in root element
- `nextSibling`
  - Returns node's next sibling
- `nodeValue`
  - Retrieves value of text node
- `parentNode`
  - Returns node's parent node



Outline

DOMExample.html (1 of 3)

Here is the root node of the document: article
The following are its child elements:
title
date
author
summary
content
The first child of root node is: title
whose next sibling is: date.
Value of date element is: July 15, 2003
Parent node of date is: article.
Done
My Computer

20.7 DOM Methods

Method	Description
`getNodeType`	Returns an integer representing the node type.
`getNodeName`	Returns the name of the node. If the node does not have a name, a string consisting of # followed by the type of the node is returned.
`getNodeValue`	Returns a string or null depending on the node type.
`getParentNode`	Returns the parent node.
`getChildNodes`	Returns a `NodeList` (Fig. 20.21) with all the children of the node.
`getFirstChild`	Returns the first child in the `NodeList`.
`getLastChild`	Returns the last child in the `NodeList`.
`getPreviousSibling`	Returns the node preceding this node, or null.
`getNextSibling`	Returns the node following this node, or null.
`getAttributes`	Returns a `NamedNodeMap` (Fig. 20.22) containing the attributes for this node.
`insertBefore`	Inserts the node (passed as the first argument) before the existing node (passed as the second argument). If the new node is already in the tree, it is removed before insertion. The same behavior is true for other methods that add nodes.

20.7 DOM Methods

`replaceChild`	Replaces the second argument node with the first argument node.
`removeChild`	Removes the child node passed to it.
`appendChild`	Appends the node passed to it to the list of child nodes.
`getElementsByTagName`	Returns a `NodeList` of all the nodes in the subtree with the name specified as the first argument ordered as they would be encountered in a preorder traversal. An optional second argument specifies either the direct child nodes (0) or any descendant (1).
`getChildAtIndex`	Returns the child node at the specified index in the child list.
`addText`	Appends the string passed to it to the last `Node` if it is a `Text` node, otherwise creates a new `Text` node for the string and adds it to the end of the child list.
`isAncestor`	Returns `true` if the node passed is a parent of the node or is the node itself.

Fig. 20.20 Some DOM `Node` object methods.

20.7 DOM Methods

Method	Description
`item`	Passed an index number, returns the element node at that index. Indices range from 0 to *length* – 1.
`getLength`	Returns the total number of nodes in the list.

Fig. 20.21 Some DOM `NodeList` methods.

Method	Description
`getNamedItem`	Returns either a node in the `NamedNodeMap` with the specified name or null.
`setNamedItem`	Stores a node passed to it in the `NamedNodeMap`. Two nodes with the same name cannot be stored in the same `NamedNodeMap`.
`removeNamedItem`	Removes a specified node from the `NamedNodeMap`.
`getLength`	Returns the total number of nodes in the `NamedNodeMap`.
`getValues`	Returns a `NodeList` containing all the nodes in the `NamedNodeMap`.

Fig. 20.22 Some DOM `NamedNodeMap` methods.

20.7 DOM Methods

Method	Description
`getDocumentElement`	Returns the root node of the document.
`createElement`	Creates and returns an element node with the specified tag name.
`createAttribute`	Creates and returns an attribute node with the specified name and value.
`createTextNode`	Creates and returns a text node that contains the specified text.
`createComment`	Creates a comment to hold the specified text.

Fig. 20.23 Some DOM `Document` methods.

20.7 DOM Methods

Method	Description
`getTagName`	Returns the name of the element.
`setTagName`	Changes the name of the element to the specified name.
`getAttribute`	Returns the value of the specified attribute.
`setAttribute`	Changes the value of the attribute passed as the first argument to the value passed as the second argument.
`removeAttribute`	Removes the specified attribute.
`getAttributeNode`	Returns the specified attribute node.
`setAttributeNode`	Adds a new attribute node with the specified name.

Fig. 20.24 Some DOM `Element` methods.

Method	Description
`getValue`	Returns the specified attribute's value.
`setValue`	Changes the value of the attribute to the specified value.
`getName`	Returns the name of the attribute.

Fig. 20.25 Some DOM `Attr` methods.

Method	Description
`getData`	Returns the data contained in the node (text or comment).
`setData`	Sets the node's data.
`getLength`	Returns the number of characters contained in the node.

Fig. 20.26 Some DOM `Text` and `Comment` methods.

20.8 Simple API for XML (SAX)

- Developed by members of XML-DEV mailing list
- Parse XML documents using event-based model
- Provide different APIs for accessing XML document information
- Invoke listener methods
- Passes data to application from XML document
- Better performance and less memory overhead than DOM-based parsers

20.9 Extensible Stylesheet Language (XSL)

- Specify how programs should render XML document data
  - XSL-FO (XSL Formatted Objects)
    - Vocabulary for specifying formatting
  - XSLT (XSL Transformation)
    - Source tree
    - Result tree
  - Xpath
    - Locate parts of the source tree document that match templates defined in the XSL stylesheet

20.9 Extensible Stylesheet Language (XSL)

Element	Description
`<xsl:apply-templates>`	Applies the templates of the XSL document to the children of the current node.
`<xsl:apply-templates match = "expression">`	Applies the templates of the XSL document to the children of *expression*. The value of the attribute `match` (i.e., *expression*) must be some XPath expression that specifies elements.
`<xsl:template>`	Contains rules to apply when a specified node is matched.
`<xsl:value-of select = "expression">`	Selects the value of an XML element and adds it to the output tree of the transformation. The required `select` attribute contains an XPath expression.
`<xsl:for-each select = "expression">`	Implicitly contains a template that is applied to every node selected by the XPath specified by the `select` attribute.
`<xsl:sort select = "expression">`	Used as a child element of an `<xsl:apply-templates>` or `<xsl:for-each>` element. Sorts the nodes selected by the `<apply-template>` or `<for-each>` element so that the nodes are processed in sorted order.
`<xsl:output>`	Has various attributes to define the format (e.g., xml, html), version (e.g., 1.2, 2.0), document type and media type of the output document. This tag is a top-level element, which means that it can be used only as a child element of a `stylesheet`.
`<xsl:copy>`	Adds the current node to the output tree.

Fig. 20.27 Commonly used XSL stylesheet elements.

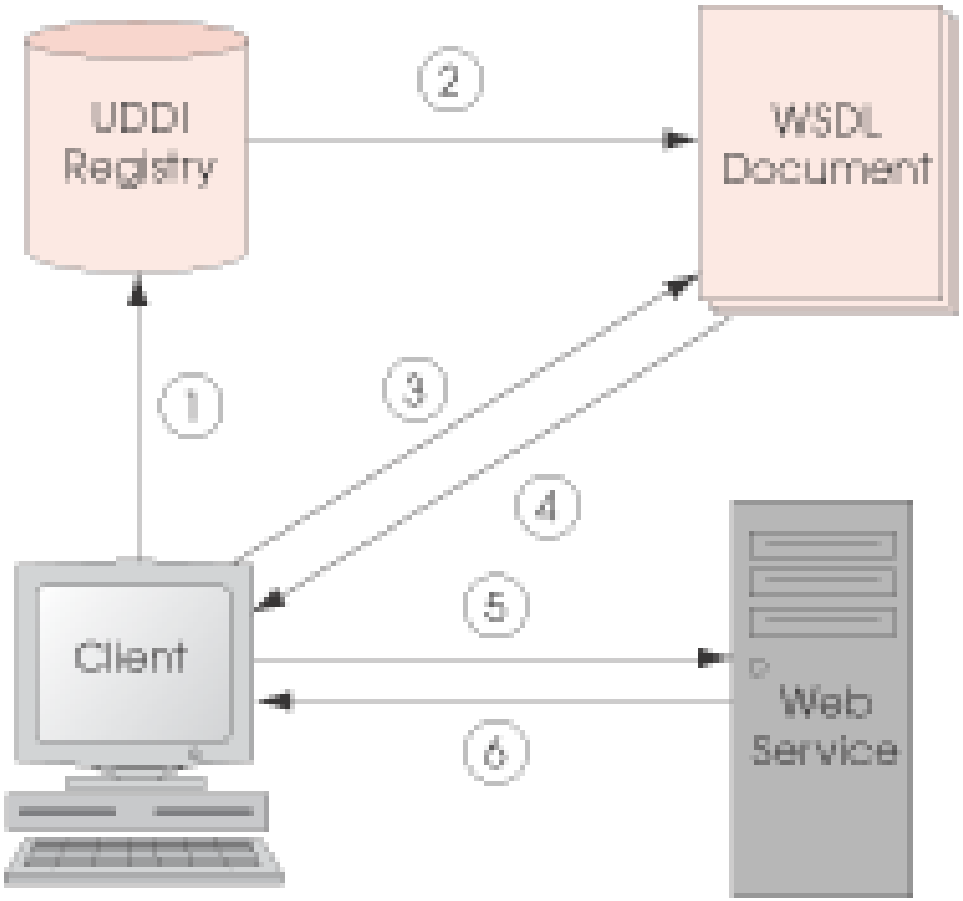
20.10 Simple Object Access Protocol (SOAP)

- Developed by IBM, Lotus Development Corporation, Microsoft, DevelopMentor, and Userland Software
- XML-based protocol
- Allows applications to communicate over Internet
- SOAP message
  - Envelope
    - A structure describes a method call
  - Body
    - Request
      - Remote Procedure Call (RPC)
    - Response
      - HTTP response document contains results from other method call

20.11 Web Services

- Standards
  - XML
  - SOAP
  - Web Services Description Language (WSDL)
  - Universal Description, Discovery and Integration (UDDI)
  - Modular programming
    - Modularization
      - Less error prone and promotes software reuse

20.11 Web Services



1. Client queries registry to locate service
2. Registry refers client to WSDL document
3. Client accesses WSDL document
4. WSDL provides data to interact with Web service
5. Client sends SOAP-message request
6. Web Service returns SOAP-message response

20.12 Water XML-Based Programming Language

- Simplifies XML and Web services programming
- Represents all objects and data as XML
